

The energy transition is generating
more data than ever.

The next challenge is knowing
what to do with it.

A modern energy asset produces a continuous stream of signal.

It arrives fragmented — across systems that were never designed to speak to each other, and formats that were never designed to be compared.

Data is abundant.
Intelligence is
scarce.

More data does not automatically create better decisions. Operators and asset managers should not have to spend hours interpreting thousands of signals to understand what actually matters.

The intelligence layer between energy infrastructure and the people responsible for it.

01

Raw data

Everything the asset already produces, at native resolution, from the systems already installed.

02

Operational intelligence

Validated, reconciled and interpreted — separating what changed from what merely moved.

03

Management visibility

One version of operational reality, legible to an engineer and to a board in the same document.

04

Action

What deserves attention, why it matters, and what should happen next.

From operational data
to operational intelligence.

Monitor. Understand. Alert. Report. Act.

01

Monitor

Continuous performance intelligence across availability, energy behaviour, equipment status and operational trends.

02

Understand

Operational information processed automatically into concise management-level insight — not one more dashboard to check.

03

Alert

Not simply that something happened, but why it matters and what deserves attention.

04

Report

Daily and monthly reporting that is automatic, standardised, transparent and traceable to its source measurement.

05

Act

Operational signal turned into maintenance priorities — what requires attention, when, and why.

Every report answers the same five questions.

What happened. Why it happened. What matters. What needs attention. What should happen next.

MANAGEMENT TRANSPARENCY

One infrastructure.
One source of operational truth.
One intelligent layer.

Executives, asset managers, owners and technical teams looking at the same operational reality — through a layer each of them can read.

1 GW

INSTALLED ENERGY-STORAGE CAPACITY

Quorelia's technology is being applied in the context of approximately 1 GW-scale BESS infrastructure.

Built and tested around real, large-scale battery energy storage operations — not a theoretical concept, and not a demonstration environment.

Built around real infrastructure.

Designed for real operations.

Two founders. A decade of building together. One problem worth the next decade.

Diego Ostertag

CO-FOUNDER & CHIEF EXECUTIVE OFFICER

Finance, business strategy and commercialisation, with a technology-oriented approach to how a company is built and taken to market. MBA in Finance from the University of Chile, with a background in marketing and business development.

Jae Hee Kim

CO-FOUNDER & CHIEF OPERATING OFFICER

Energy infrastructure, renewables, technology and international business, with direct experience in large-scale solar operations and in building systems that turn complex operational information into management intelligence — across data, automation and AI.

Diego and Jae Hee have built businesses together for roughly ten years, across several industries, before converging on a single observation: critical infrastructure produces enormous quantities of data, and the people responsible for it still struggle to turn that data into something simple, transparent and actionable.

Quorelia was born from that problem.

The future of energy will not only be renewable. It will be intelligent.

Infrastructure is becoming more complex — solar, storage, hybrid assets, grid interaction. Management cannot scale by adding more dashboards and more people. The next generation of infrastructure will observe, understand, communicate and recommend.

We are working with energy infrastructure stakeholders who want to see what intelligent operations can look like.

Let's build the next layer of energy infrastructure together.
